

MULTIWAVELENGTH CASCADED RAMAN RESONATOR

PRIORITY APPLICATION

This application claims priority from a provisional U.S. patent application, Serial Number 60/275,261, filed on March 12, 2001, hereby incorporated by reference.

FIELD OF THE INVENTION

The present invention relates to Raman resonators.

10

BACKGROUND OF THE INVENTION

Raman amplifiers and resonators are known in the field of optical communications. These devices rely on the Raman effect. When light is transmitted through matter, part of the light is scattered in random directions. A small part of the scattered light has frequencies removed from the frequency of the incident beam by quantities equal to vibration frequencies of the material scattering system. This small part is called Raman scattering. If the initial beam is sufficiently intense and monochromatic, a threshold can be reached beyond which light at the Raman frequencies may be amplified, generally exhibiting the characteristics of stimulated emission. This stimulated emission is commonly referred to as the stimulated Raman scattering.

One device employing the Raman effect is a cascaded Raman resonator (“CRR”). Generally, a CRR receives radiation from a source pump at a particular wavelength, λ_{pump} , and shifts the radiation through one or more steps to a desired output wavelength, λ_{out} , where λ_{out} is greater than λ_{pump} . While various types of CRRs exist, one type currently being examined is a fiber-based CRR, which shifts the wavelength of the pump light in an optical fiber. Fiber-based

CRRs are capable of providing higher power in a single mode fiber than single mode semiconductor diodes. To date, fiber-based CRRs have been used for remote pumping of Er-doped fiber amplifiers, and as pumps for Raman amplifiers.

5 In an optical fiber, the gain curve from the Raman effect is relatively broad, yet not particularly flat over a wide frequency range. To obtain a flat gain curve, a Raman amplifier may be pumped using several different wavelengths, each triggering the Raman effect. The gain profile of such a Raman amplifier is effectively the superposition of the gain of each of the
10 individual pumps, in addition to the interaction between the pumps. Presently, these pumps have been realized by multiplexing a number of semiconductor laser diodes or CRRs together. Multiplexing schemes, however, add additional cost to the overall device and place wavelength and polarization limitations on the semiconductor diodes. The power required from each single wavelength device
15 is modest when compared to the total power that a CRR is capable of producing. However, the total power in all of the wavelengths is comparable to that obtainable from a CRR. It has therefore been advantageous to turn the large amount of power available at a single wavelength of a CRR into power at multiple wavelengths.

20 One practical solution for making a multiple wavelength cascaded Raman resonator (“MWCRR”) has been to variably distribute power over the output wavelengths. This approach has been disadvantageous because the tolerances imposed by a system on the wavelength power ratio of a MWCRR are tighter than the possible manufacturing tolerances. Moreover, the specifications
25 imposed by the system also depend on the final assembly of the system. The performance of the system, consequently, may be enhanced by dynamically controlling the wavelength power ratio and, hence, the shape of the gain curve.

As such, a need remains for the ability to control the wavelength power ratio of a MWCRR.

SUMMARY OF THE INVENTION

We have invented a method for controlling the relative wavelength power distribution in a Raman device, such as, for example, a MWCRR. In accordance with the present invention, an optical device employs at least one output coupler having a reflectivity which may be independently varied or tuned to compensate or achieve a desired power distribution. The reflectivity of the output coupler may be modified using various means, including, for example, applying a non-uniform stress, heat or a voltage/current.

In one example of the present invention, a Raman device, such as, for example, a MWCRR, comprises at least one set of optical gratings coupled with at least a first and a second output coupler for controlling the relative wavelength power distribution. Here, each output coupler has a reflectivity which varies in response to the application of a non-uniform stress, heat or a voltage/current.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be better understood from reading the following description of non-limiting embodiments, with reference to the attached drawings, wherein below:

FIG. 1(a) is a schematic diagram of the quantum mechanical behavior of Raman scattering, while **FIG. 1(b)**, is a graphical illustration of the Raman gain spectrum in an optical fiber;

FIG. 2(a) is a schematic view of a known cascaded Raman resonator, while **FIG. 2(b)** is a graphical illustration of the reflectivity versus wavelength for another known cascaded Raman resonator of **FIG. 2(a)**;

FIG. 3 is a schematic view of an embodiment of the present invention;
FIG. 4 is a schematic view of a feature of the present invention;
FIG. 5 is a graphical illustration of the reflectivity versus wavelength of
the feature depicted in **FIG. 4**;
5 **FIG. 6** is a graphical illustration of the in-band optical power versus
wavelength of an example of the embodiment of **FIG. 3**;
FIG. 7 is a schematic view of another embodiment of the present
invention; and
10 **FIG. 8** is a schematic view of yet another embodiment of the present
invention.

It should be emphasized that the drawings of the instant application are
not to scale but are merely representations of the invention, which may be
determined by one of skill in the art by examination of the information contained
herein.

15

DETAILED DESCRIPTION

Referring to **FIG. 1(a)**, a schematic diagram of the quantum mechanical
behavior of Raman scattering is illustrated. Raman scattering is a process by
which light incident on a medium is converted to light at a lower frequency than
20 the incident light. A pump photon, ν_p , may be excited up to a virtual level (e.g.,
non-resonant state). The pump photon decays to a lower energy level emitting a
photon, ν_s , relatively quickly during this process. The difference in this energy
translates into molecular vibrations having a number of levels. It is these levels
that determine the shape of a Raman gain curve.

25 Referring to **FIG. 1(b)**, a graphical illustration of the Raman gain
spectrum in an optical fiber is shown. Here, the normalized gain in an optical
fiber is depicted as a function of the frequency shift created by the Raman effect.

Due to the amorphous nature of silica fibers, the Raman gain spectrum is relatively broad. Because the pump photon is excited to a virtual level, the Raman gain can occur for a pump source at any wavelength. In Ge-doped silica fibers, the peak of this gain will occur at a frequency about 13 THz away from
5 the frequency of the input light.

Referring to FIG. 2(a), a schematic view of a known cascaded Raman resonator (“CRR”) 10 is shown. CRR 10 may be employed in conjunction with an optical multiplexer, for example, to provide optical gain over a number of wavelengths. More particularly, CRR 10 comprises an optical source 15, such
10 as a pump laser (e.g., Ytterbium-doped cladding pumped fiber laser lasing in the 1060-1200 nm region), for generating continuous wave (“CW”) optical radiation at a first wavelength λ_1 . Coupled with source 15 are one or more individual input gratings 20. Each of the one or more input gratings 20 has a reflectivity. In one example, the reflectivity of each input grating 20 is between about eighty
15 (80%) percent and one-hundred (100%) percent — though other operable reflectivities are contemplated herein — and is commonly referred to as a “high reflector.” Input gratings 20 are written into a first end of an optical waveguide 25, such as a Raman gain medium (e.g., Raman fiber). Alternatively, input gratings 20 may be spliced onto the first end of an optical waveguide 25. As
20 shown, each grating from input gratings set 20 are centered at second, third, fourth, fifth and sixth wavelengths λ_2 , λ_3 , λ_4 , λ_5 , and λ_6 .

CRR 10 also comprises one or more output gratings 30. Output gratings 30 are written into or spliced onto a second end of optical waveguide 25. Output gratings 30 are coupled with input gratings 20 by an intermediate section of optical waveguide 25. Much like input gratings 20, each grating of output gratings 30 comprises a high reflector. Each high reflector of output gratings 30 is centered at an individual wavelength λ_1 , λ_2 , λ_3 , λ_4 , and λ_5 .

Coupled with output gratings set **30** is at least one output coupler **35**. Output coupler **35** comprises at least one grating centered at sixth wavelength λ_6 . Unlike input and output gratings, **20** and **30**, the grating of output coupler **35** has a relatively lesser reflectivity. In one example, output coupler **35** has a reflectivity of less than about eighty (80%) percent. In so doing, output coupler **35** allows optical radiation at sixth wavelength λ_6 to propagate out from CRR **10**.

Operationally, CRR **10** receives CW optical radiation at first wavelength λ_1 from optical source **15**. The CW optical radiation at first wavelength λ_1 propagates through input gratings **20**, and is converted within optical waveguide **25** to second wavelength, λ_2 , and from second wavelength, λ_2 , to third wavelength, λ_3 , and from third wavelength, λ_3 , to fourth wavelength, λ_4 , and from fourth wavelength, λ_4 , to fifth wavelength, λ_5 , and from fifth wavelength, λ_5 , to sixth wavelength, λ_6 , by means of the Raman effect. Input gratings **20**, here, improve the efficiency of CRR **10** by reflecting forward any backscattered light back into optical waveguide **25**. Any optical radiation propagating through output gratings **30** at first, second, third, fourth and fifth wavelengths, λ_1 , λ_2 , λ_3 , λ_4 , and λ_5 , are reflected back through optical waveguide **25** by one of the high reflectors centered at wavelengths λ_1 , λ_2 , λ_3 , λ_4 , and λ_5 in output gratings **30**. Consequently, optical radiation at first, second, third, fourth, and fifth wavelengths — λ_1 , λ_2 , λ_3 , λ_4 , λ_5 — emanates from optical waveguide **25** reflected back to optical waveguide **25** by one of the gratings of output gratings **30**. By this design, optical radiation having a wavelength other than sixth wavelength, λ_6 , is nominally blocked from escaping a cavity forming CRR **10**. Consequently, input and output gratings, **20** and **30**, effectively convert the wavelength (e.g., λ_1) of the optical radiation from optical source **15** to a higher wavelength (e.g., λ_6). This higher wavelength (e.g., λ_6) is dependent on

selecting the center wavelength of the high reflectors of input and output gratings, 20 and 30, as well as the center wavelength of output coupler 35.

Referring to FIG. 2(b), a graphical illustration of the reflectivity versus wavelength for a known multiple wavelength CRR (“MWCRR) design is illustrated. In this known MWCRR approach, the wavelength power ratio of the MWCRR is controlled by shifting the center wavelength of the output coupler. This deliberate shifting is effectuated by misaligning the cavity of the MWCRR at a particular wavelength. In so doing, the efficiency of the cavity at the particular wavelength is reduced, thereby lowering the power emitted at the particular wavelength. The results of such an implementation are characterized in the graphical illustration of FIG. 2(b).

Referring to FIG. 3, a schematic view of an embodiment of the present invention is illustrated. Here, a solution is realized for wavelength power distribution control in a MWCRR, for example, without shifting the center wavelength of the output coupler(s). We have recognized that the reflectivity of the output coupler may be controlled, for example, by writing a chirped or unchirped grating into an optical waveguide, such as a Raman optical fiber, of the MWCRR. The optical waveguide in which these gratings are written into or spliced onto may also be coated with a metal. Consequently, the peak reflectivity of these gratings may be decreased by applying a stress, heat (e.g., uniform or non-uniform) or an electrical voltage/current to the coating of the metal of the particular chirped gratings. Likewise, upon removing the stress, heat or electrical voltage/current, the peak reflectivity of these gratings may be relatively increased. As such, the amount of light that may be extracted from the cavity of an MWCRR at a predetermined wavelength may be controlled in accordance with the principles of the present embodiment.

More particularly, the schematic view of FIG. 3 shows a multiple wavelength CRR (“MWCRR”) 100 employing the principles of the present

embodiment. MWCRR 100 comprises a pump optical source 105, such as a cladding pumped fiber laser, for generating continuous wave (“CW”) optical radiation at a first wavelength λ_1 (e.g., 1100 nm). Coupled with pump optical source 105 are a first and second set of input gratings, 110 and 115. Each of the 5 one or more gratings in both sets of input gratings, 110 and 115, may be chirped or unchirped and realized by a high reflector. In one example, the reflectivity of each grating in both sets of input gratings, 110 and 115, is between about eighty (80%) percent and one-hundred (100%) percent — though other operable reflectivities are contemplated herein. Both sets of input gratings may be written 10 into or spliced onto a first end of an optical waveguide 120, such as a Raman gain medium (e.g., optical fiber). Unlike CRR 10 of FIG. 2(a), the first set of input gratings 110 have been included because of their feedback properties to allow lasing in MWCRR 100. Each grating in both sets of input gratings, 110 and 115, are centered at a second, third, fourth, fifth, sixth, seventh and eighth 15 wavelength λ_2 (e.g., 1153 nm), λ_3 (e.g., 1211 nm), λ_4 (e.g., 1275 nm), λ_5 (e.g., 1347 nm), λ_6 (e.g., 1425 nm), λ_7 (e.g., 1455 nm), and λ_8 (e.g., 1480 nm).

MWCRR 100 also comprises one or more output gratings 125. Output gratings 125 are written into or spliced onto a second end of optical waveguide 120. Output gratings 125 are coupled with both sets of input gratings, 110 and 115, by an intermediate section of optical waveguide 120. Each grating of 20 output gratings 125 comprises a high reflector. Furthermore, output gratings 125 are centered at the second wavelength, λ_2 (e.g., 1153 nm), third wavelength, λ_3 (e.g., 1211 nm), fourth wavelength, λ_4 (e.g., 1275 nm), and fifth wavelength, λ_5 (e.g., 1347 nm).

Coupled with output gratings 125 and written into or spliced onto further 25 along the second end of optical waveguide 120 are a number of adjustable output couplers 130. It should be apparent to skilled artisans that alternative

configurations may also be operative. For example, output couplers **130** may also be positioned in between optical waveguide **120** and output gratings **125**.

Each adjustable output coupler **130** comprises an element having variable reflectivity centered at the sixth wavelength, λ_6 (e.g., 1425 nm), the seventh wavelength, λ_7 (e.g., 1455 nm), and the eighth wavelength, λ_8 (e.g., 1480 nm). In one example, the element within each adjustable output coupler **130** is realized by a chirped or unchirped grating. The reflectivity of each adjustable output coupler **130** is controlled by an individual control system **135**. In one example, each control system **135** is realized by a stressing or heating source, or, alternatively, an electrical power source for generating a voltage or current, to modify the reflectivity of its respective adjustable output coupler **130**. Each control system **135** modifies the percentage of optical radiation propagation transmitted through its respective adjustable output coupler **130**, and therefore the reflectivity of the respective adjustable output coupler **130**. Consequently, the amount of optical radiation propagating from the cavity of MWCRR **100** at particularly desirable wavelengths is now controllable. As such, the wavelength power ratio and the shape of the gain curve of MWCRR **100** may be dynamically controlled.

Referring to FIG. 4, a schematic view of a feature of the present invention is illustrated. More particularly, FIG. 4 shows one example of an adjustable output coupler **150**, which may be used in MWCRR **100** of FIG. 3. Adjustable output coupler **150** comprises an optical fiber **155**, such as, for example, a Raman gain medium (e.g., Raman fiber), having a standard coating **175**. Written into or spliced onto optical fiber **155** is a grating **170**. Grating **170** may be chirped or unchirped. Surrounding grating **170** is temperature responsive tapered metal coating **160**, in contrast with standard coating **175**. Metal coating **160** is coupled with a power source **180** for increasing the

temperature of grating 170. The increase in the temperature of grating 170 corresponds with the amount of tapered metal at a given point along metal coating 160 in contact with grating 170, as well as the amount of an electrical current applied thereto. The peak reflectivity of grating 170 may be decreased 5 by applying an electrical voltage/current to metal coating 160 surrounding grating 170. Upon removing the electrical voltage/current from metal coating 160, the peak reflectivity of these gratings may be relatively increased. It should be apparent to skilled artisans that various voltage/current levels generated by power source 180 will correspondingly vary the temperature of grating 170, and thusly, its peak reflectivity. Consequently, the peak reflectivity of grating 170 10 may be changed by applying stress or heat. In one example, the stress or heat applied to grating 170 by power source 180 is non-uniform.

Referring to FIG. 5, a graphical illustration of the reflectivity versus wavelength (λ) of an exemplary adjustable output coupler, such as coupler 150 15 of FIG. 4, is shown.

Referring to FIG. 6, a graphical illustration of the in-band optical power versus wavelength (λ) of an exemplary MWCRR, such as MWCRR 100 of FIG. 3, is shown. From this graphical illustration, as the voltage applied to an adjustable output coupler centered at the eighth wavelength, λ_8 , of 1480 nm is 20 increased, the output power at that wavelength decreases. Consequently, it should be apparent to skilled artisans that similar results may be obtained by changing the voltage applied to adjustable output couplers centered at the sixth or seventh wavelengths, λ_6 or λ_7 , of 1425 nm or 1455 nm, respectively.

Referring to FIG. 7, a schematic view of another embodiment of the 25 present invention is illustrated. Here, an optical apparatus 200 is shown for varying the intensity of optical radiation for a single wavelength over a number of output lines. More particularly, optical apparatus 200 comprises an optical

source **205**, such as a pump laser, for generating continuous wave (“CW”) optical radiation at a first wavelength λ_0 . The CW optical radiation from optical source **205** is divided by a splitter **207** into N number of lines (**210₁**, **210₂** through **210_N**), where N is greater than or equal to two.

5 Each line in optical apparatus **200** comprises a high reflector (**215₁**, **215₂** through **215_N**), coupled with an adjustable output coupler (**225₁**, **225₂** through **225_N**) by means of an optical waveguide (**220₁**, **220₂** through **220_N**), such as a Raman optical fiber. Each adjustable output coupler is centered around the same individual wavelength (e.g., λ_1). Alternatively, each adjustable output coupler may be centered around individual wavelengths (e.g., λ_1 , λ_2 through λ_N) — depending on the purpose of the dividing the optical radiation. The output from each adjustable output coupler is fed into an optical amplifier (**230₁**, **230₂** through **230_N**) to generate N number of outputs (**OUTPUT₁**, **OUTPUT₂** through **OUTPUT_N**). Consequently, the power level (e.g., intensity) of each output may be adjusted, as such, by varying each adjustable output coupler. As a result, the outputs (**OUTPUT₁**, **OUTPUT₂** through **OUTPUT_N**) may have individual power levels or intensities (I_1 , I_2 through I_N). Moreover, the adjusted power level of the outputs may be centered around the same wavelength (λ_1), or individual wavelengths (e.g., λ_1 , λ_2 through λ_N).

20 Referring to **FIG. 8**, a schematic view of another embodiment of the present invention is illustrated. Here, an optical apparatus **300** for selecting the power distribution of at least two wavelengths. More particularly, optical apparatus **300** comprises an optical source **305**, such as a pump laser, for generating continuous wave (“CW”) optical radiation at a first wavelength λ_0 . The CW optical radiation from optical source **305** is divided by a splitter **307** into N number of lines (**310₁**, **310₂** through **310_N**) where N is greater than or equal to two.

Each line in optical apparatus 300 comprises a high reflector (315₁, 315₂ through 315_N), coupled with an adjustable output coupler (325₁, 325₂ through 325_N) by means of an optical waveguide (320₁, 320₂ through 320_N), such as a Raman optical fiber. Since each adjustable output coupler is centered around an individual wavelength (λ_1 , λ_2 through λ_N). The output lines (330₁, 330₂ through 330_N) from each adjustable output coupler are each fed to a combiner 335 for combining the optical radiation at each individual wavelength (λ_1 , λ_2 and λ_N) into a single line output (OUTPUT). Consequently, power level of each of the individual wavelengths (λ_1 , λ_2 through λ_N) may be adjusted within the single line output (OUTPUT) by varying one or more of the adjustable output couplers (325₁, 325₂ through 325_N).

While the particular invention has been described with reference to illustrative embodiments, this description is not meant to be construed in a limiting sense. It is understood that although the present invention has been described, various modifications of the illustrative embodiments, as well as additional embodiments of the invention, will be apparent to one of ordinary skill in the art upon reference to this description without departing from the spirit of the invention, as recited in the claims appended hereto. It is therefore contemplated that the appended claims will cover any such modifications or embodiments as fall within the true scope of the invention.
